

In patients with a low probability of PE who fulfill all eight criteria, the likelihood of PE is low and no further testing is required. All other patients should be considered for further testing with sensitive D ...

Always double CHECK inputs and computer-generated outputs, data processing and original sources manually. Normal values presented here are only a general guide. It is essential to check the values ...

To enable clinicians to confidently rule out PE while reducing the number of unnecessary CTPAs, several clinical rules have been developed and validated.

Supportive care is a critical component of managing hematologic emergencies, including those that may involve thrombotic or bleeding complications. Understanding the PERC rule can aid in the triage and ...

There is no need to apply the PERC rule to those patients who are not being evaluated for PE. If the patient is considered low-risk, PERC may help avoid further testing.

The PERC rule, which consists of eight clinical criteria including history, physical and vital signs, can then be used. If both of these criteria are met, then there is less than a 2 percent risk that ...

If the patient is considered low risk, the PERC Rule may help avoid further testing. If the patient is moderate or high risk, then PERC Rule cannot be utilized.

Check all of the following that are true: In patients with low suspicion for PE (best-guess pre-test probability <15%) AND all are true, only 0.9% had PE (n=7527) and it can be ruled-out without further ...

This rule is a screening tool with high sensitivity, but low specificity. In other words, a patient meeting all of the PERC criteria has a very low likelihood of having a PE, but a person failing to meet all of the ...

We found that PERC rule is highly effective in ruling out the PE in settings of low clinical suspicion and D-dimer testing is therefore unnecessary when the pretest probability is low.
